

3DIO X THE MISFITS SOFTWARE

FROM PAINTED CANON TO A LIVING RIG.

A product pilot for turning canonical character art into rigged, animatable assets for a working 2.5D game runtime.

Private discussion material - 31 August 2026

Two games already run. MoAD is the character test bed.

MYSTERY OF ANCIENT DARKNESS

A painted 2.5D occult action-adventure set in 1935. Lord Conrad and Lady Alice Compton have seven days to follow their stolen son through Prague, Cairo and a valley of sealed tombs.

- Playable Windows pre-alpha 0.3.5
- Custom runtime and visual level editor
- RURK-powered combat and persistent consequences
- 67-page illustrated narrative prelude

TANKS OF THEA

A story-driven tank roguelike RPG. The player commands people inside armour instead of driving a vehicle directly; crews and autonomous units interpret orders through their own skills, condition and AI.

- Playable Windows alpha 08u
- Game and standalone map editor
- Single player, Melee, LAN and original 2D prototype
- Studio-trained persistent TankBrain seed

The engine works. The character pipeline is the wound.

MoAD's environments, runtime, traversal logic, combat and authoring tools already exist. The remaining visual risk is repeatable character production: preserving the canonical face and body while generating enough motion for a cinematic adventure.

01

CANON

Approved art locks identity, proportions, clothing, weapons and material language.

02

3DIO

Image or multi-view input becomes a textured model; rigging and editing are the critical claims to verify.

03

RIG

One stable skeleton supports a growing animation library instead of hundreds of unrelated drawings.

04

OUTPUT

Use the model directly in 3D, or render clean 2.5D frames from controlled cameras and lighting.

05

RUNTIME

Import into our editor, bind metadata, validate scale, collision, weapons and gameplay states.

If this chain holds, a new character or costume becomes an asset operation - not a fresh animation crisis.

The faces are not suggestions.

3DIO is not being asked to invent generic adventurers. The pilot must reconstruct two named, canonical adults whose identity survives rotation, relighting and motion.

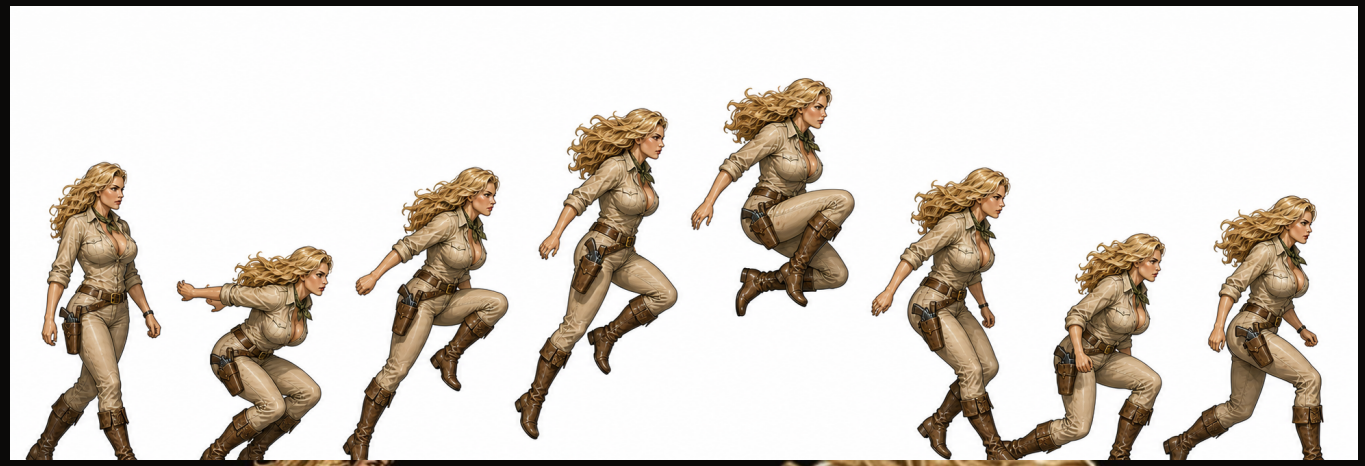

LADY ALICE COMPTON

- Face: mature, intelligent, severe - never doll-like
- Body: canonical proportions must remain stable
- Hair: long dense curls, visually important in silhouette
- Wardrobe: fitted expedition clothes, belts, holster, boots
- Motion: athletic but physical; weight and recovery matter

LORD CONRAD COMPTON

- Face: powerful, weathered, recognisable at gameplay scale
- Body: 1.98 m, heavy movement profile
- Wardrobe: layered shirt, harness, holster, boots
- Weapon identity: modified Webley Mk VI

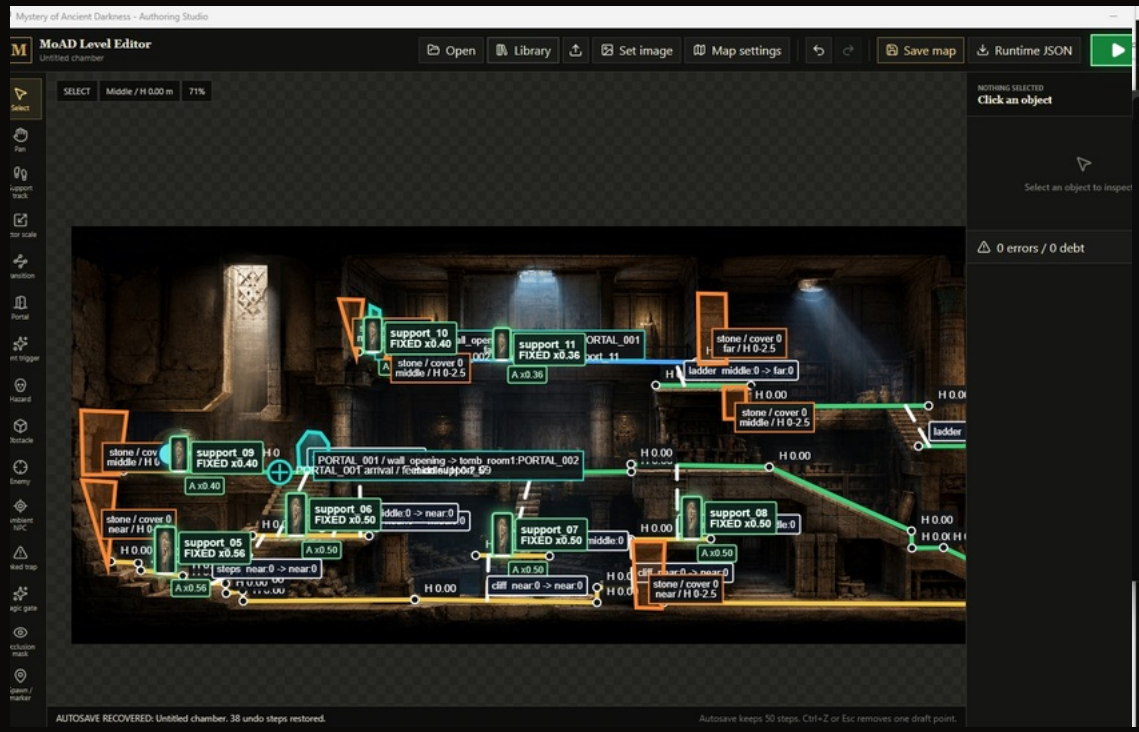

One skeleton. A library instead of a landfill.

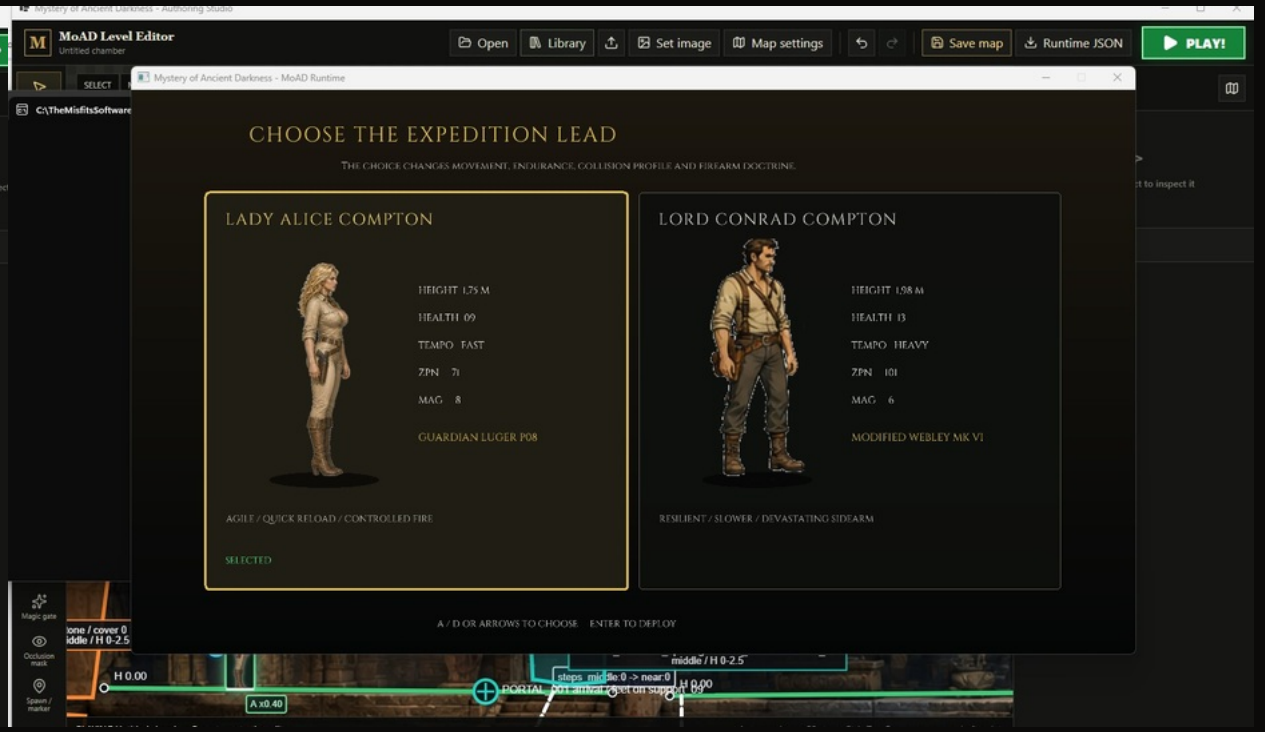

The current sprite pipeline proves the required verbs but not the desired finish. A successful rig lets the library grow coherently: idle, walk, run, jump, crouch, climb, ledge, balance, aim, fire, reload, damage and transformation states.

This is where the model must land.

AUTHORING STUDIO

RUNTIME CHARACTER CONTRACT

- Scale and pivot metadata
- Actor collision profile
- Animation state mapping
- Depth lane and occlusion behaviour
- Weapon sockets and timing
- Editor preview and one-click playtest

Do not promise us a pipeline. Let us break one together.

INPUT

- Canonical Alice portrait
- Full-body scale reference
- Jump keypose sheet
- Runtime sprite frames
- Optional 10-100 generated orthographic views
- Clothing and weapon references

3DIO OUTPUT

- Textured GLB
- Humanoid skeleton
- Documented bone names and hierarchy
- Stable materials and UVs
- One editable project/workspace
- API job identifiers and reproducible settings

MISFITS TEST

- Blender structural audit
- Godot import
- Retarget idle/walk/run/jump
- Extreme-pose deformation test
- 2.5D camera render
- Runtime scale/pivot/socket integration

Pilot success means the same Alice survives the entire chain - not merely that a GLB file appears.

Pretty in the viewer is not production-ready.

IDENTITY	Face, body and silhouette remain recognisably canonical from front, profile and 3/4 views.
TOPOLOGY	No catastrophic intersections, detached surfaces or unusable density; polygon count is reported.
RIG	Consistent humanoid hierarchy, clean transforms, named bones, predictable rest pose and export.
WEIGHTS	Shoulders, elbows, wrists, hips, knees, chest and clothing survive extreme poses.
MATERIALS	Textures and UVs export correctly; skin, fabric, leather and metal remain separable.
ANIMATION	At least idle, walk, run and jump retarget without repair that destroys the time advantage.
INTEGRATION	GLB imports into Blender and Godot; scale, pivot, sockets and animation clips remain intact.
RIGHTS	Commercial game use, derivative renders, local modification and shipped output are explicitly permitted.
AUTOMATION	The same inputs and settings can be repeated through documented API/SDK calls.

The questions between a demo and a production dependency.

- Does 'Skeleton to GLB' mean automatic rigging of generated humanoids, and what skeleton standard is used?
- Are skin weights generated automatically? Can the rig and weights be edited and re-exported?
- Are facial bones or blendshapes available? If not, is facial rigging on the roadmap?
- Can one canonical character be regenerated across outfits while preserving face, body and skeleton identity?
- Can existing animations be retargeted, and which interchange standards are supported?
- Which PBR maps, UV guarantees, LOD tools, polygon controls and mesh repair tools are exposed?
- What are the API endpoints, authentication model, job lifecycle, quotas, retention policy and versioning guarantees?
- Can generation remain private? Are customer inputs or outputs used for training?
- Who owns generated models and derivatives, and are shipped commercial games explicitly covered?
- What would a white-label or co-development agreement look like for a small studio acting as a demanding showcase partner?

3DIO gets a live production problem. We get our characters back.

THE MISFITS PROVIDES

- Canonical characters and hard references
- Working runtime and editors
- Real production feedback
- Public credit and logo placement after success
- A demanding case study across 3D and 2.5D

3DIO PROVIDES

- Pilot access and technical onboarding
- Rigging/export clarification
- API/SDK documentation
- Engineering contact for blocked cases
- A path from trial to sustainable licensing

MUTUAL OPTION

- Technology partnership
- Co-authorship or investment discussion
- Joint showcase
- White-label integration
- Case study only by mutual approval

Tanks latest 08u: https://themisfitssoftware.itch.io/tanks-of-thea

Next step: generate one canonical Alice, rig her, retarget four clips, import into Godot, and review the wreckage together.
